

## a. Architectural Characteristics

	<b>Characteristic</b>
<b>Availability</b>	The system must be available 24/7 for customers and experts to submit and track tickets.
<b>Scalability</b>	The system must handle spikes in ticket volume and user access during high-demand periods.
<b>Reliability / Fault Tolerance</b>	The system should continue operating even when one microservice or component fails.
<b>Performance</b>	Responses (ticket creation, assignment, updates) must happen within seconds.
<b>Modifiability / Maintainability</b>	The system should support frequent changes without affecting other components.
<b>Security</b>	Authentication and authorization for customers, experts, and admins; secure payments and personal data.
<b>Auditability</b>	All ticket updates, assignments, and billing transactions should be logged.
<b>Usability</b>	Web and mobile apps must be user-friendly for both customers and Sysops experts.
<b>Interoperability</b>	Integration with SMS, email notification, and payment systems.

## b. Scenarios per Characteristic

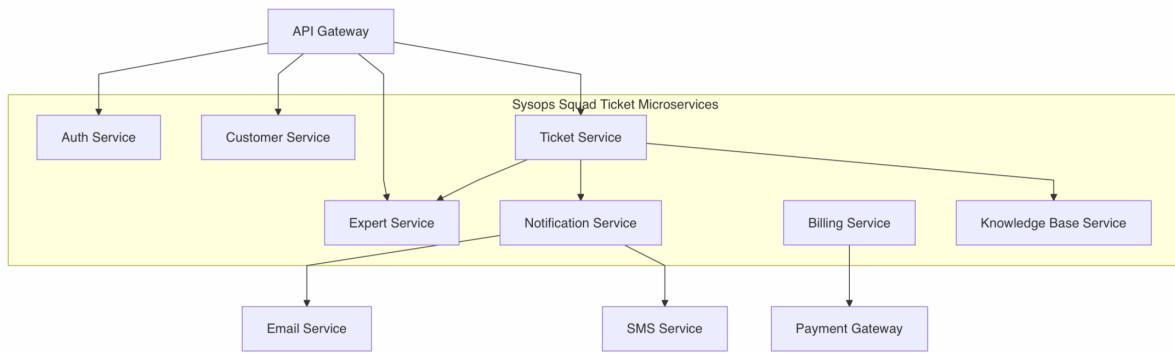

<b>Characteristic</b>	<b>Scenario</b>
<b>Availability</b>	If one microservice fails (ex. Notification Service), others like Ticket or Expert Service should continue running; retry mechanism for notifications.
<b>Scalability</b>	During a product recall, when thousands of customers submit tickets, the system auto-scales via container orchestration (Kubernetes).
<b>Reliability</b>	When a database replica fails, the service continues using a secondary replica.
<b>Performance</b>	Ticket assignment occurs within 2 seconds after a customer submits a request.
<b>Modifiability</b>	A new “priority level” field can be added to tickets without redeploying all services.
<b>Security</b>	Only registered customers can create tickets; only authorized experts can access them.
<b>Auditability</b>	Admin can query the system to see which expert handled which ticket on which date.
<b>Usability</b>	Experts access tickets easily via a responsive mobile app interface.
<b>Interoperability</b>	The system integrates seamlessly with Twilio (SMS) and Mailgun (email).

## c. Architecture Definition (Diagrams)

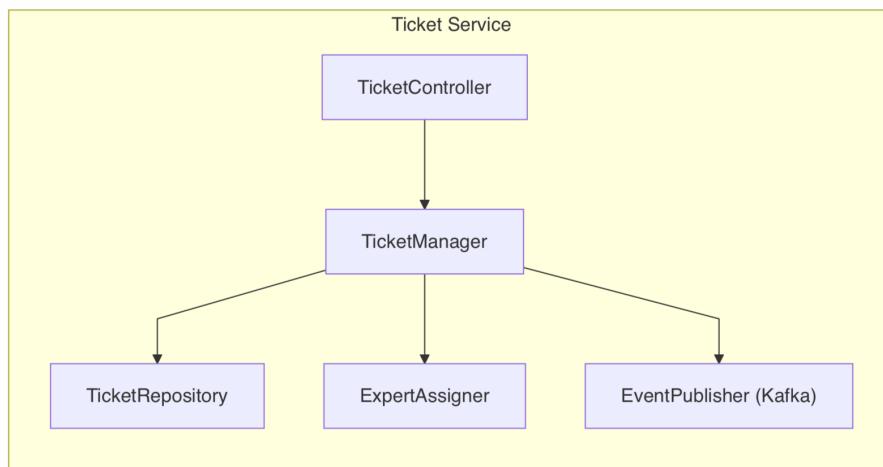

## 1. Context Diagram

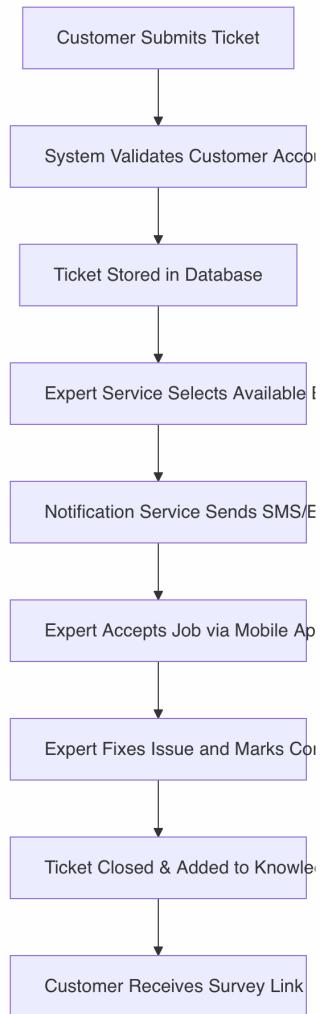

## 2. Container Diagram

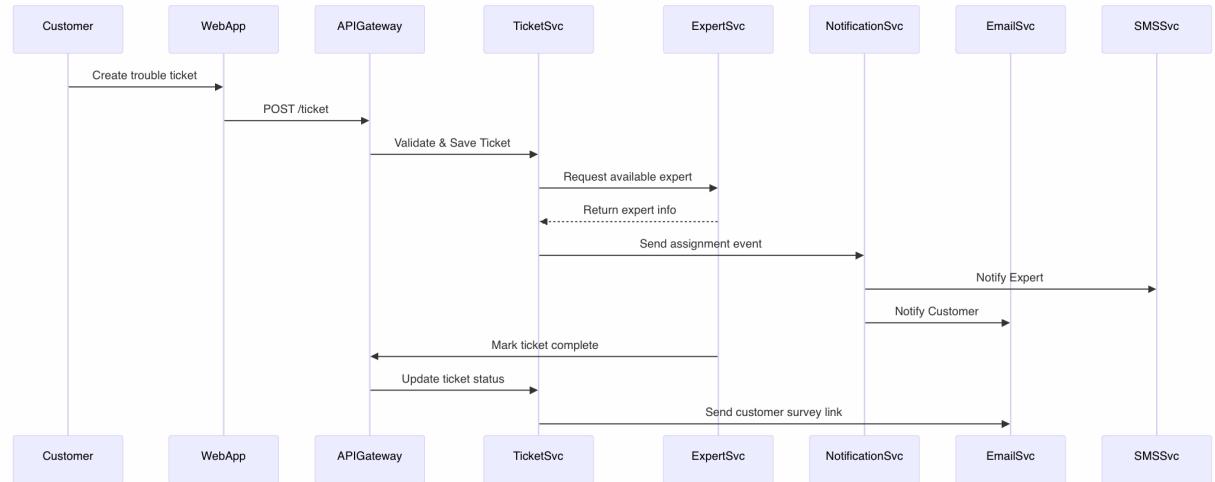

## 3. Component Diagram (for Ticket Service)

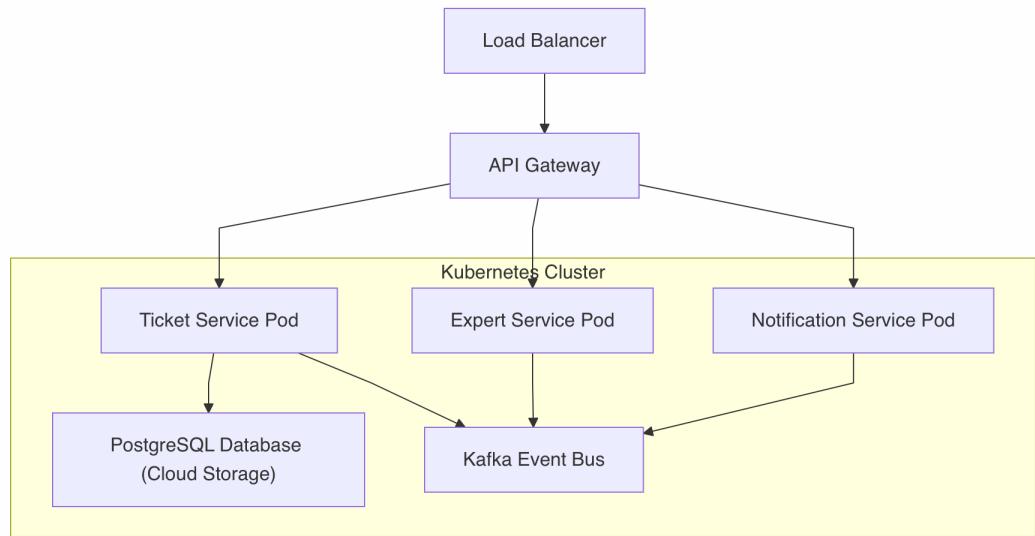

#### 4. Activity Diagram (Ticket Lifecycle)

## 5. Sequence Diagram (End-to-End Ticket Flow)

## 6. Deployment Diagram (Optional – for completeness)

### d. Risks of the Proposed Architecture

Risk	Description	Impact
<b>Integration Failure</b>	Email/SMS/Payment services may be unavailable or slow.	Missed notifications or delayed billing.
<b>Data Inconsistency</b>	Ticket or expert data may become inconsistent if services fail mid-transaction.	Wrong assignments or lost tickets.
<b>Performance Bottlenecks</b>	Improperly scaled Ticket Service could delay responses.	Customer dissatisfaction.
<b>Security Breach</b>	Unauthorized access or data leakage.	Legal and financial penalties.
<b>Complex Deployment</b>	Microservices increase deployment complexity.	DevOps overhead and potential downtime.
<b>Message Loss in Queue</b>	Kafka event loss or duplication.	Missed expert notifications or duplicate assignments.

### e. Risk Mitigation Options

Risk	Mitigation Strategy
<b>Integration Failure</b>	Implement retry policies, circuit breakers, and service fallback responses.
<b>Data Inconsistency</b>	Use distributed transactions (Saga pattern) and event-driven consistency.
<b>Performance Bottlenecks</b>	Apply horizontal auto-scaling and caching layers (Redis).
<b>Security Breach</b>	Use OAuth2, JWT authentication, TLS encryption, and RBAC.
<b>Complex Deployment</b>	Automate CI/CD pipeline with Docker + Kubernetes + Helm charts.
<b>Message Loss</b>	Enable Kafka message persistence, acknowledgments, and dead-letter queues.
